Trend Study 25R-1-04

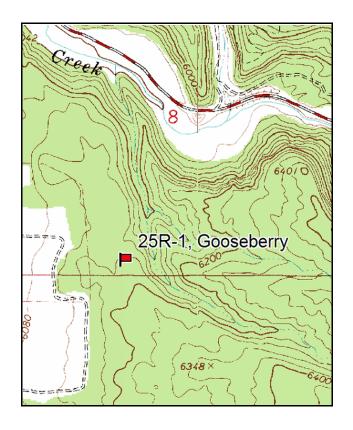

Study site name: <u>Gooseberry</u>. Vegetation type: <u>Pinyon-Juniper</u>.

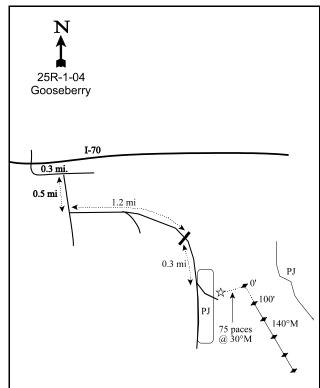

Compass bearing: frequency baseline 140 degrees magnetic.

Frequency belt placement: line 1 (11ft), line 2 (34ft), line 3 (59ft), line 4 (71ft), line 5 (95ft).

LOCATION DESCRIPTION

Take exit #61 from I-70 and turn south. Go 0.3 miles to a right turn. Take this turn and go 0.5 miles to a left (east) turn. Take this turn and go 0.6 miles to a fork. Take the left fork and go 0.6 miles to a gate. Go another 0.3 miles past the gate to a small road leading into the chaining. The half-high witness post is located inside the chaining where the road ends. The browse tag for the transect is #150.

Map name: Gooseberry Creek.

Township 22 S, Range 2 E, Section 32

DISCUSSION

Gooseberry - Trend Study No. 25R-1

The Gooseberry study site was established in 1997 prior to being chained in the fall of 1997. The chaining was done to improve wildlife habitat to try and prevent deer from going onto nearby alfalfa fields to the west. Prior to treatment, the site was dominated by pinyon and juniper situated on a northwest aspect at an elevation of 6,200 feet with a 7% slope. It presently supports a few heavily grazed seeded grasses and forbs. Pellet group data from 1997 estimated 13 deer (33 ddu/ha) and 18 elk days use/acre (45 edu/ha). Pellet group data from 2004 estimated 40 cows days use/acre (98 cdu/ha). Cow use was from late spring to early summer.

The soil is a light brown loam texture and has a neutral pH (7.1). Organic matter is moderately high at 4.0%. Rock is prevalent on the surface and throughout the profile, resulting in an estimated effective rooting depth of just under 11 inches. The rocks have a calcium carbonate coating and a calcium carbonate layer was found in the soil at about 11 inches. Bare ground was relatively low before the chaining at about 20% in and increased to 46% in 2004. Litter before the chaining made up 62% of the ground cover and dropped to 30% by 2004. Typically litter is greater after a chaining and the differences is the slash from the chaining was piled into clumps. Erosion is minimal due to the heavily armored surface from pavement and rock. The erosion condition class determined soil movement as stable in 2004.

Pinyon and juniper was the dominate browse species before the chaining and accounted for 68% of the total vegetation cover. Before the chaining, pinyon was estimated at 104 trees/acre with an average diameter of 5.4 inches. Juniper was estimated at 112 trees/acre with an average diameter of 19.1 inches. There is still good cover of pinyon and juniper surrounding the site. No preferred browse was observed before or after the chaining and only broom snakeweed was found after the chaining. The high percentage of bare ground creates the potential for broom snakeweed to expand rapidly.

Prior to the chaining, the herbaceous understory was dominated by cheatgrass and a few native grasses such as Indian ricegrass and bottlebrush squirreltail. Forbs consisted of a few small annual species. The herbaceous understory accounted for 27% of the total vegetation cover before the chaining and increased to 93% after the chaining. Perennial grasses such as crested wheatgrass and intermediate wheatgrass established well after the chaining, although were heavily utilized by cows earlier in the summer. Cheatgrass was still found on the site, but decreased significantly from 1997 observations. Alfalfa is the dominate forb and makes up 27% of the total vegetation cover.

The original goal of this project was to keep deer off of the alfalfa fields by creating better habitat in the pinyon/juniper zone. Unfortunately, pellet group data suggest that no deer or elk are using the site. It would appear that there is some conflict with management if the area was treated to create habitat for deer, but cows are utilizing all the forage. Continued heavy livestock use will continue to decrease the value of this site.

2004 TREND ASSESSMENT

Trend for soil is down. Percent bare ground increased from 20% in 1997 to 46% in 2004. Litter from chaining was collected in large piles, which is not as effective at reducing erosion or creating safe sites for seed establishment. Trend for browse species is slightly down. No preferred browse species are found on this site and with broom snakeweed on the site it may rapidly become a weed problem. Trend for herbaceous understory is up. Perennial grasses and forbs increased significantly and provide protection for the soil. Heavy use by cows was observed, and if continued may have detrimental effects on this site. The Desirable Components Index rated this site as very poor with a score of 27 due to no preferred shrub cover and moderate to good perennial grass and forb cover.

TREND ASSESSMENT

soil - down (1)

<u>browse</u> - slightly down (2)

<u>herbaceous understory</u> - up (5)

1997 winter range condition (DC Index) - 6 (very poor) P-J chaining type 2004 winter range condition (DC Index) - 27 (very poor) P-J chaining type
